

# Max-flow Problem

---

## Text

---

The visualization so is an example of computing the max flow in the graph. So we start with this network if given its capacities, and initially without this flow from S to A to D, the flow volume is 1, and as you see the capacity of those two ounces has decreased by

one. The algorithm proceeds iteratively by routing additional flows through the network

until it cannot find a path from S to T with residual capacity. As you can see, this is the case at this point. There is no other path at this point that he has available capacity from S to T.
